Type Package

Title Multivariate Bayesian Model with Shrinkage Priors

Version 4.0

Date 2023-05-17

Author Ray Bai, Malay Ghosh

Maintainer Ray Bai <raybaistat@gmail.com>

Description Gibbs sampler for fitting multivariate Bayesian linear regression with shrinkage priors (MBSP), using the three parameter beta normal family. The method is described in Bai and Ghosh (2018) <[doi:10.1016/j.jmva.2018.04.010](https://doi.org/10.1016/j.jmva.2018.04.010)>.

matrix_normal	<i>Matrix-Normal Distribution</i>
---------------	-----------------------------------

Description

This function provides a way to draw a sample from the matrix-normal distribution, given the mean matrix, the covariance structure of the rows, and the covariance structure of the columns.

Usage

```
matrix_normal(M, U, V)
```

Arguments

M	mean $a \times b$ matrix
U	$a \times a$ covariance matrix (covariance of rows).
V	$b \times b$ covariance matrix (covariance of columns).

Details

This function provides a way to draw a random $a \times b$ matrix from the matrix-normal distribution,

$$MN(M, U, V),$$

where M is the $a \times b$ mean matrix, U is an $a \times a$ covariance matrix, and V is a $b \times b$ covariance matrix.

Value

A randomly drawn $a \times b$ matrix from $MN(M, U, V)$.

Author(s)

Ray Bai and Malay Ghosh

Examples

```
# Draw a random 50x20 matrix from MN(0,U,V),
# where:
#   0 = zero matrix of dimension 50x20
#   U has AR(1) structure,
#   V has sigma^2*I structure

# Specify Mean.mat
p <- 50
q <- 20
Mean_mat <- matrix(0, nrow=p, ncol=q)

# Construct U
rho <- 0.5
times <- 1:p
H <- abs(outer(times, times, "-"))
U <- rho^H

# Construct V
sigma_sq <- 2
V <- sigma_sq*diag(q)

# Draw from MN(Mean_mat, U, V)
mn_draw <- matrix_normal(Mean_mat, U, V)
```

Description

This function provides a fully Bayesian approach for obtaining a (nearly) sparse estimate of the $p \times q$ regression coefficients matrix B in the multivariate linear regression model,

$$Y = XB + E,$$

using the three parameter beta normal (TPBN) family. Here Y is the $n \times q$ matrix with n samples of q response variables, X is the $n \times p$ design matrix with n samples of p covariates, and E is the $n \times q$ noise matrix with independent rows. The complete model is described in Bai and Ghosh (2018).

If there are r confounding variables which *must* remain in the model and should *not* be regularized, then these can be included in the model by putting them in a separate $n \times r$ confounding matrix Z . Then the model that is fit is

$$Y = XB + ZC + E,$$

where C is the $r \times q$ regression coefficients matrix corresponding to the confounders. In this case, we put a flat prior on C . By default, confounders are not included.

If the user desires, two information criteria can be computed: the Deviance Information Criterion (DIC) of Spiegelhalter et al. (2002) and the widely applicable information criterion (WAIC) of Watanabe (2010).

Usage

```
MBSP(Y, X, confounders=NULL, u=0.5, a=0.5, tau=NA,
      max_steps=6000, burnin=1000, save_samples=TRUE,
      model_criteria=FALSE)
```

Arguments

Y	Response matrix of n samples and q response variables.
X	Design matrix of n samples and p covariates. The MBSP model regularizes the regression coefficients B corresponding to X .
confounders	Optional design matrix Z of n samples of r confounding variables. By default, confounders are not included in the model (confounders=NULL). However, if there are some confounders that <i>must</i> remain in the model and should <i>not</i> be regularized, then the user can include them here.
u	The first parameter in the TPBN family. Defaults to $u = 0.5$ for the horseshoe prior.
a	The second parameter in the TPBN family. Defaults to $a = 0.5$ for the horseshoe prior.

<code>tau</code>	The global parameter. If the user does not specify this (<code>tau=NA</code>), the Gibbs sampler will use $\tau = 1/(p * n * \log(n))$. The user may also specify any value for τ strictly greater than 0; otherwise it defaults to $1/(p * n * \log(n))$.
<code>max_steps</code>	The total number of iterations to run in the Gibbs sampler. Defaults to 6000.
<code>burnin</code>	The number of burn-in iterations for the Gibbs sampler. Defaults to 1000.
<code>save_samples</code>	A Boolean variable for whether to save all of the posterior samples of the regression coefficients matrix B and the covariance matrix Σ . Defaults to "TRUE".
<code>model_criteria</code>	A Boolean variable for whether to compute the following information criteria: DIC (Deviance Information Criterion) and WAIC (widely applicable information criterion). Can be used to compare models with (for example) different choices of u , a , or τ . Defaults to "FALSE".

Details

The function performs (nearly) sparse estimation of the regression coefficients matrix B and variable selection from the p covariates. The lower and upper endpoints of the 95 percent posterior credible intervals for each of the pq elements of B are also returned so that the user may assess uncertainty quantification.

In the three parameter beta normal (TPBN) family, $(u, a) = (0.5, 0.5)$ corresponds to the horseshoe prior, $(u, a) = (1, 0.5)$ corresponds to the Strawderman-Berger prior, and $(u, a) = (1, a)$, $a > 0$ corresponds to the normal-exponential-gamma (NEG) prior. This function uses the horseshoe prior as the default shrinkage prior.

The user also has the option of including an $n \times r$ matrix with r confounding variables. These confounders are variables which are included in the model but should *not* be regularized.

Finally, if the user specifies `model_criteria=TRUE`, then the MBSP function will compute two model selection criteria: the Deviance Information Criterion (DIC) of Spiegelhalter et al. (2002) and the widely applicable information criterion (WAIC) of Watanabe (2010). This permits model comparisons between (for example) different choices of u , a , and τ . The default horseshoe prior and choice of τ performs well, but the user may wish to experiment with u , a , and τ . In general, models with *lower* DIC or WAIC are preferred.

Value

The function returns a list containing the following components:

<code>B_est</code>	The point estimate of the $p \times q$ matrix B (taken as the componentwise posterior median for all pq entries).
<code>B_CI_lower</code>	The 2.5th percentile of the posterior density (or the lower endpoint of the 95 percent credible interval) for all pq entries of B .
<code>B_CI_upper</code>	The 97.5th percentile of the posterior density (or the upper endpoint of the 95 percent credible interval) for all pq entries of B .
<code>active_predictors</code>	The row indices of the active (nonzero) covariates chosen by our model from the p total predictors.
<code>B_samples</code>	All <code>max_steps</code> - <code>burnin</code> samples of B .

C_est	The point estimate of the $r \times q$ matrix C corresponding to the confounders (taken as the componentwise posterior median for all rq entries). This matrix is not returned if there are no confounders (i.e. confounders=NULL).
C_CI_lower	The 2.5th percentile of the posterior density (or the lower endpoint of the 95 percent credible interval) for all rq entries of C . This is not returned if there are no confounders (i.e. confounders=NULL).
C_CI_upper	The 97.5th percentile of the posterior density (or the upper endpoint of the 95 percent credible interval) for all rq entries of C . This is not returned if there are no confounders (i.e. confounders=NULL).
C_samples	All max_steps-burnin samples of C . This is not returned if there are no confounders (i.e. confounders=NULL).
Sigma_est	The point estimate of the $q \times q$ covariance matrix Σ (taken as the componentwise posterior median for all q^2 entries).
Sigma_CI_lower	The 2.5th percentile of the posterior density (or the lower endpoint of the 95 percent credible interval) for all q^2 entries of Σ .
Sigma_CI_upper	The 97.5th percentile of the posterior density (or the upper endpoint of the 95 percent credible interval) for all q^2 entries of Σ .
Sigma_samples	All max_steps-burnin samples of C .
DIC	The Deviance Information Criterion (DIC), which can be used for model comparison. Models with smaller DIC are preferred. This only returns a numeric value if model_criteria=TRUE is specified.
WAIC	The widely applicable information criterion (WAIC), which can be used for model comparison. Models with smaller WAIC are preferred. This only returns a numeric value if model_criteria=TRUE is specified. The WAIC tends to be more stable than DIC.
